

Beta-delayed Charged particles : Peering into Nuclear Structure

María José García Borge

Instituto de Estructura de la Materia, CSIC

Nuclear Landscape

Desintegration β^+ -EC

Desintegration β^-

Desintegration α

Fission

β -decay process

- β^\pm -decay gives first glance on the structure by the half-life
- Detailed spectroscopy gives the microscopic structure

$$B_{GT} = \left| \langle \psi_f | \sum \sigma \tau^\pm | \psi_i \rangle \right|^2$$

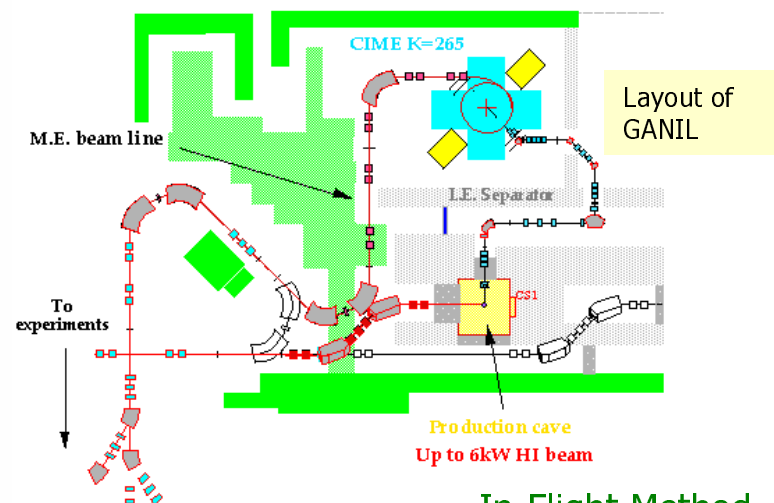

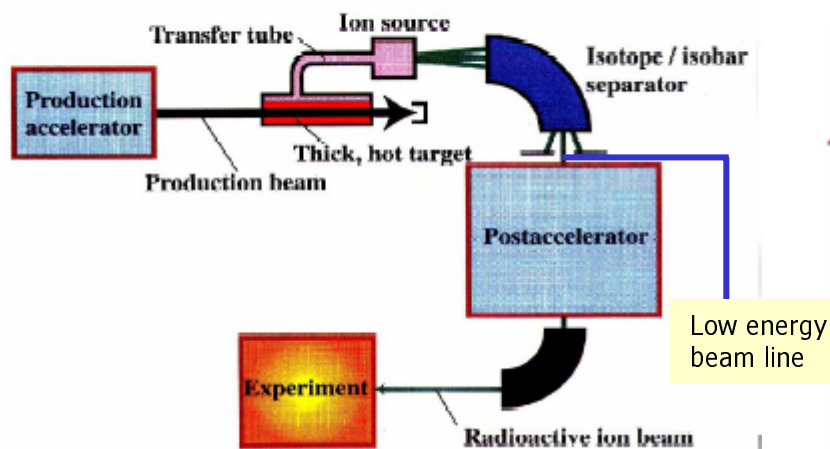

$$B_F = \left| \langle \psi_f | \sum \tau^\pm | \psi_i \rangle \right|^2$$

Production of Exotic Nuclei

Projectile Fragmentation

ISOL

In-Flight Method

- ✓ Short separation times
- ✓ Direct determination of B.R.
- ✓ High efficiency due to deep implantation on detectors
- ✓ Simultaneous Measurement of several nuclei

ISOLDE

- ✓ Low energy beams
- ✓ Good Optics
- ✓ Chemical separation means

Decay properties of exotic nuclei

➤ Global properties

- Short half-lives ($\sim ms$)

- High Q_β values
- Low $S_{p/n}$ values

➔ β -delayed particle emission

➤ β^+ (C.E.) emission

- β -delayed particle spectrum depends:
 - beta-feeding to the unbound levels in emitter
 - Probability to emit the charged particle

- Reduced transition probability:

$$ft = f * \frac{T_{1/2}}{B.R.} = \frac{K}{G_V^2 |\tau|^2 + G_A^2 |\sigma\tau|^2} = \frac{C}{B(F) + B(GT)}$$

➤ **1916** Rutherford & Wood $\beta\alpha$ [*Philos. Mag.* **31** (1916) 379]

➤ **1963** Barton & Bell identified ^{25}Si as βp

✓ Impressive reproduction of the excited structure and B_{GT} distribution by Shell Model calculation

✓ Extraction of the quenching factor of the axial-vector coupling constant

Search for New Physics

- ✓ e-v correlation a good probe of weak interactions
- ✓ The V-A character of β -decay determined by measuring e-v correlation through the daughter recoil in 1963
- ✓ Improved precision to find new physics by using $\beta\beta$ emitter . e-v correlation determined from the broadening of proton peak from IAS in $0^+ \rightarrow 0^+$ transitions
- ✓ Supersymmetry and Models with lepto-quarks predicts scalar contributions to the weak interactions.

- Isospin mixing in Fermi decays
- Limit for scalar component in beta decays $|C_A/C_V|^2 < 3.6 \times 10^{-3}$

- Absolute branching ratios /MSU
- Very precise $T_{1/2}$ determination /ISOLDE
- $ft = 1552(12)$ s for the Fermi decay
- Isospin Symmetry breaking Correction $\delta_c = 2.0(4) \%$

^{31}Ar β -2p emitter

Decay of IAS through 2p emission

Diagonal from decays via single intermediate state from many initial states fed in beta-decay

Surprise at the neutron drip line: Halo nuclei

1985, First experiments with radioactive nuclear beams, Berkeley (USA)

Be, C and Al

Tanihata

$$\sigma_I(p, t) = \pi[R_I(p) + R_I(t)]^2$$

$R_m(^{11}\text{Li}) = 3.30(24) \text{ fm}$

 $R_c(^{11}\text{Li}) = 2.47(4) \text{ fm}$

Why is the mass radius so large?

Hansen & Jonson

Europhys. Lett. 4 (1987) 287

✓ Energy threshold effect ($S_{2n} = 378(5) \text{ keV}$)

✓ Highlight by nuclear reactions

✓ Effects in beta decay

Beta decay of an exotic nuclei

Even a neutron rich - nuclei emit charged particles

1983
15.721
 $^8\text{Li} + t$

1980
8.982
 $2\alpha + 3n$

1979
7.315
 $^9\text{Be} + 2n$

1974
0.504
 $^{10}\text{Be} + n$

1996
17.916

$Q = 20.54 \text{ MeV}$,
 $T_{1/2} = 8.2 \text{ ms}$
 $b(320) = 6.3(6) \%$

$$(1s_{1/2})^2 / (0p_{1/2})^2 \sim 1$$

Beta-delayed deuterons

$$Q_{\beta d} = 3.007 - S_{2n} \text{ MeV}$$

B.R. Two Orders of Magnitude less than expected

First case of β -decay to the continuum

^{11}Li β d spectrum finally measured @ TRIUMF!!

DSSSD 16x16 mm², 70μm thick
 48x48 strips, 300 μm, 2304 pixels
 J. Büscher et al., NIM B in press

- Implantation of ^{11}Li beam on DSSSD Detector
- Very precise B.R.
- Low detection threshold
- Low beta background
- History of each decay

B.R = $1.30(13) \times 10^{-4}$

$E_{\text{cm}} > 200$ keV

Deuteron Spectrum

Decay to the continuum confirmed

Exotic Radioactivities

1p-radioactivity

$$(Z, N) \rightarrow p + (Z-1, N)$$

2p-radioactivity

$$(Z, N) \rightarrow 2p + (Z-2, N)$$

These nuclei at the edge of nuclear existence highlight various phenomena related to the binding of nucleons in the nucleus

1 Proton Radioactivity

- ✓ Proton-radioactivity from gs fixed the proton drip-line of this region.
- ✓ First observed in ^{151}Lu & ^{147}Tm (1981 @ GSI)
- Emission of protons only from odd- $Z \in [50-83]$, 28 g.s. proton emitters identified.
- The sensitivity of $T_{1/2}$ to angular momentum allows for the assignment of the orbital from which the proton is emitted.
- As protons are detected with high efficiency, proton emitters are used to identify nuclei in Recoil Decay Tagging (RDT).
- p-emission from *highly deformed* nuclei has been observed and decay rates explained assuming Nilsson states.
- Stringent test of shell model beyond drip line.

Two proton Radioactivity

Predicted in
 the 60's by
 Goldanskii as
 consequence of
 the pairing
 force \Rightarrow easier
 to eject the
 pair that break
 it apart

Found 2002

By Bordeaux &
Warsaw

Miernik et al,
 NIM A 581 (2007) 194
 PRL 99 (2007) 192501
 PRC 76 (2007) 041304R

2p-correlations
observed in 2007

Mirror Asymmetry ?

- Charge independence hypothesis of nuclear interactions:
symmetry of analog β transitions

$$\beta^- : n \rightarrow p + e^- + \bar{\nu}$$

$$ft^\pm = \frac{K}{g_V^2 B_F^\pm + g_A^2 B_{GT}^\pm}$$

$$K/g_V^2 = 6146(6)s \quad g_A^2/g_V^2 = 1.587(3)$$

$$\beta^+ : p \rightarrow n + e^+ + \nu$$

$$\text{E.C.} : p + e^- \rightarrow n + \nu$$

- Isospin symmetry breaking \Rightarrow asymmetry in mirror β -decays

$$\delta = \frac{ft^+}{ft^-} - 1$$

$$\delta = \delta_{\text{nuc}} + \delta_{\text{SCC}}$$

Systematics of experimental δ values ($A \leq 40$)

➤ **Allowed Gamow-Teller transitions ($\log(ft) < 6$)**

→ **17 couples of nuclei**

→ **46 mirror transitions**

Thomas et al., AIP Conf. Proc 681, p. 235

Average asymmetry δ :

{ 11 (1) % in the 1p shell ($A < 17$)
 0 (1) % in the (2s,1d) shell ($17 < A < 40$)

First identification of a proton-halo state

Rolfs, NPA217(73)29

$$\delta = ft^+/ft^- - 1 = -0.55(09)$$

Borge et al., PLB317(93)25

Asymmetry ↔ Halo Structure

A = 9 Isobar

Large asymmetries

$$\delta = \frac{(ft)^+}{(ft)^-} - 1$$

Nyman et al., NPA 510 (1990) 189

Mikolas et al., PRC 37 (1988) 766

F. Ajzenberg-Selove, NPA 490 (1988) 1

Why to Study Light Nuclei ?

➤ **"Exact"** A-body calculations possible for $A \leq 12$

Green Function Monte-Carlo methods

Non-core Shell-model

➤ **Crucial** for bridging $A=5$ and $A=8$ gaps in

Big Bang and Stellar nuclear synthesis

The $\alpha(\alpha n, \gamma)^9\text{Be} + ^9\text{Be}(\alpha, n)^{12}\text{C}$

Competes with triple- α in n-rich scenarios

Importance of the $\alpha + n \leftrightarrow ^5\text{He}(\alpha, \gamma)^9\text{Be}$

➤ Experimentally **β -decay** provides

Clean way to feed **unbound** states

Break-up mechanism not fixed by kinematics

^9B States fed in β -decay of ^9C

$$E_{\text{sum}} = \frac{M_{\text{recoiling}} + M_{\text{first}}}{M_{\text{recoiling}}} E_{\text{first}} + x \begin{cases} = 92 \text{ keV (9/8) for } ^8\text{Be}(0^+) & \text{---} \\ \approx 2 \text{ MeV (9/5) for } ^5\text{Li}(3/2^-) & \text{---} \\ = 3.0 \text{ MeV (9/8) for } ^8\text{Be}(2^+) & \text{---} \end{cases}$$

- Sequential Decay of 12.2 MeV State via $^8\text{Be}(\text{gs})$, $^8\text{Be}(2^+)$, $^5\text{Li}(\text{gs})$ and $^5\text{Li}(1/2)$

- R-Matrix-formalism applied.

- MC-simulations to account for efficiencies of each channel

- Results E: 12.19(4) MeV

Γ : 450(20) keV

J: 5/2

B_{GT} : 1.20(15)

Summary

- ❑ Decay modes: peering into nuclear structure
- ❑ Exotics decays: testing shell model beyond the drip line
 peering into nucleon-nucleon correlations
- ❑ Large Asymmetries: ^{17}Ne , ^{17}N halo structure
 ^9C , ^9Li coupling to the continuum
- ❑ Level densities \longrightarrow Fluctuations \longrightarrow Chaos
 \downarrow
 Relevant for astrophysics

The future is bright!

With the power of the new accelerators
 And the developments in detectors
 We will discover new structures and
 characterize the immense amount of
 new nuclei

Thanks

for your Attention!!
